## A Table of the First Factor for Prime Cyclotomic Fields

## By Morris Newman

Abstract. The first factor of the prime cyclotomic fields for all primes < 200 is computed by means of a determinantal formula, correcting some errors in tables of Kummer.

Let p = 2m + 1 be an odd prime. Let  $\zeta$  be a primitive pth root of unity, and let R be the field of rationals. It is well known that if h is the class number of the cyclotomic field  $R(\zeta)$ , and  $h_0$  the class number of the totally real subfield  $R(\zeta + 1/\zeta)$ , then h is divisible by  $h_0$ . The quotient  $h/h_0$  is denoted by  $h^*$ , and is known as the first factor of h. A complete discussion of these matters is to be found in the beautiful book [1] by Borevič and Šafarevič, where a table (uncredited) of  $h^*$  is given for all odd primes p < 100. Presumably, this table is due to Kummer, who computed  $h^*$  for all odd primes p < 163 (see [2] and [3]). The numbers p < 163 is given for all compute, and it is of some interest to verify and to extend the above-mentioned tables. The importance of p < 163 stems from the fact that the prime p > 163 is irregular if and only if p > 163 divides p > 163.

It turns out that Kummer's tables are not error-free: the values of  $h^*$  corresponding to p = 103, 139, and 163 are incorrect. The fact that p = 103 is irregular, and was correctly identified to be so by Kummer, is explicable by his method of computation.

Let g be a primitive root modulo p. Define

$$g_n = g^n - p[g^n/p], \quad n = 0, 1, 2, \cdots$$

Let  $\theta$  be a primitive (p-1)st root of unity. Then the first factor  $h^*$  is given by the formula

$$h^* = \frac{1}{(2n)^{m-1}} F(\theta) F(\theta^3) \cdots F(\theta^{p-2}),$$

where

$$F(x) = \sum_{n=0}^{p-2} g_n x^n$$
.

Kummer expresses  $h^*$  as the product of norms

$$h^* = \frac{1}{(2n)^{m-1}} \prod_{d \mid m : d \text{ odd}} N\{F(\theta^d)\},$$

and computes each rational integral factor  $N\{F(\theta^d)\}$  separately. Thus an error in the computation of  $h^*$  can occur without violating the divisibility (or nondivisibility)

Key Words and Phrases. Cyclotomic fields, class numbers, tables, factorizations.

of  $h^*$  by p, if the error occurs in the proper place. Notice that the formula above indicates that if m has many odd divisors, then  $h^*$  can be expected to have many factors.

The number  $h^*$  can also be expressed as a determinant. The companion matrix of the  $m \times m$  diagonal matrix diag  $(\theta, \theta^3, \dots, \theta^{p-2})$  is the generalized permutation matrix

$$Q = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ & \ddots & \ddots & & \\ 0 & 0 & 0 & \cdots & 1 \\ -1 & 0 & 0 & \cdots & 0 \end{bmatrix}$$

which of course is nonderogatory and satisfies  $Q^m + I = 0$ . Therefore, the determinant of the matrix F(Q) is just  $(2p)^{m-1}h^*$ , and this leads (after some elementary rearrangements) to the formula

$$(2p)^{m-1}h^* = |\det (A)|,$$

$$A = (g_{m+i+j} - g_{i+j}), \quad 0 \le i, \quad j \le m-1,$$

given as problem 5 on p. 367 of [1].

This formula is somewhat unsatisfactory however, because of the occurrence of the factor  $(2p)^{m-1}$ . This can be remedied very simply by taking into account the relationships

$$g_{i+j} \equiv g_i g_i \mod p$$
,  $g_{i+m} + g_i = p$ .

Subtract row 0 of A from every other row. A factor 2 now occurs throughout the last m-1 rows. Remove this factor of  $2^{m-1}$ , and then subtract  $g_j$  times column 0 from column j,  $1 \le j \le m-1$ . A factor p now occurs throughout the last m-1 columns. Remove this factor of  $p^{m-1}$ . The result is that

$$h^* = |\det(B)|, \quad B = (b_{ij}), \quad 0 \le i, \quad j \le m-1,$$

where

$$\begin{array}{ll} b_{00} = p - 2 \; , \\ b_{0j} = 1 - g_j \; , & 1 \leq j \leq m - 1 \; , \\ b_{i0} = 1 - g_i \; , & 1 \leq i \leq m - 1 \; , \\ b_{ij} = (g_i g_j - g_{i+j})/p \; , & 1 \leq i, j \leq m - 1 \; . \end{array}$$

The computation of  $\det(B)$  for all odd primes < 200 was carried out as a test of a program of the author's which finds the exact solution of a system of linear equations with whole number coefficients, and which also produces the determinant of the system. Storage requirements limit the program to systems of 100 equations or less, which is sufficient to accommodate the above mentioned primes. The program incorporates a check by direct multiplication which guarantees the accuracy

of the results obtained. In addition, it is known that the irregular primes under 200 are p = 37, 59, 67, 101, 103, 131, 149, 157; and in each of these instances  $h^*$  is divisible by p, furnishing an additional check on the computation. For p = 157,  $h^*$  is divisible by  $p^2$ , as was already noticed by Kummer [3]. This suggests the conjecture: There are infinitely many primes p such that  $h^*$  is divisible by  $p^2$ , or indeed

by any given power of p. The conjecture is true for the first power, since it is known that there are infinitely many irregular primes. Vandiver has proved that  $h^*$  is divisible by  $p^2$  if and only if there are integers a, b such that  $1 \le a < b \le m-1$ , and the numerators of the Bernoulli numbers  $B_{2a}$ ,  $B_{2b}$ , are each divisible by p.

Table 1 gives the values of p and  $h^*$ . Table 2 gives the factorization of  $h^*$ , and was computed by D. H. Lehmer. The author had determined all prime factors  $< 10^{5}$  of  $h^{*}$ , but was unable to produce all factors, because of lack of machine time. Professor Lehmer kindly remedied this situation.

There are some interesting points in the tables. Thus for p under 200,  $h^*$  is even only for p = 29, 113, 163, and 197; and in all of these cases  $h^*$  is divisible by 4. There is thus a distinct possibility that  $h^*$  is never singly even. Also  $h^*$  is composite for all primes p such that  $59 \le p \le 199$ , prompting the somewhat dubious conjecture that  $h^*$  is always composite except for finitely many p. Also  $h^*$  is square-free in 29 of the 45 cases given; and  $29/45 = .64444 \cdot \cdot \cdot \cdot$  does not compare too badly with  $6/\pi^2 = .60792 \cdot \cdot \cdot$ 

The computation of Table 1 was carried out on the computer of the National Bureau of Standards, and required approximately 30 minutes of machine time.
